Human Color Vision

By Peter K. Kaiser and Robert M. Boynton

Through the application of scientific method for about four hundred years, substantial progress has been made toward an understanding of how human beings are able to appreciate and gauge the colors of things. Before that, such understanding had been wholly lacking. The principal aim of this book is to put forth some of our current concepts about the nature of such color perception. With the general reader as well as the formal student in mind, I have tried to build each chapter from fundamentals without assuming any special back-ground beyond that furnished by some lower-division study of general science and mathematics. *Copyright 1996*

Abstract

Vector beams, beams with a non-uniform state of polarization, have become an indispensable tool in many areas of science and technology. Harnessing topological light properties paves the way to control and manipulate light-matter interactions at different levels, from the quantum to macroscopic physics. Here we generate tabletop extreme ultraviolet (EUV) vector beams driven by high-order harmonic generation (HHG). Our experimental and theoretical results demonstrate that HHG imprints the polarization state of the fundamental (infrared) beam, ranging from radial to azimuthal, into the higher frequency radiation. Our numerical simulations also demonstrate that the generated high-order harmonic beams can be synthesized into attosecond vector beams in the EUV/soft x-ray regime. Our proposal overcomes the state-of-the-art-limitations for the generation of vector beams far from the visible domain and could be applied in fields such as diffractive imaging, EUV lithography, or ultrafast control of magnetic properties.
